# Random Backoff in CSMA/CA

CSMA/CA (carrier sensing multiple access with collision avoidance) relies on distributed random backoff to resolve channel collisions.

Binary exponential backoff is widely used in existing standards, e.g.,

- 802.3 (Ethernet)
- 802.11 (WiFi)
- 802.15.4 (ZigBee)

### **Backoff Misbehavior**

However, a node may not always obey the binary exponential backoff. Backoff misbehavior: a selfish node purposely reduces its backoff time to gain more access to the channel.

• can lead to severe unfairness, and even denial-of-service.

### Backoff Misbehavior

However, a node may not always obey the binary exponential backoff. Backoff misbehavior: a selfish node purposely reduces its backoff time to gain more access to the channel.

• can lead to severe unfairness, and even denial-of-service.

Snapshot from jperf for comparison between throughputs of misbehaving and legitimate nodes.

Existing Work focused mainly on design of countermeasures to backoff misbehavior.

 Much work assumed a particular backoff misbehavior model and provided countermeasure to it. [Kyasanur'05, Guang'08, Rong'06]

Recent work [Radosavac'08] pointed out that we should focus more on backoff misbehaviors with significant gains.

Existing Work focused mainly on design of countermeasures to backoff misbehavior.

 Much work assumed a particular backoff misbehavior model and provided countermeasure to it. [Kyasanur'05, Guang'08, Rong'06]

Recent work [Radosavac'08] pointed out that we should focus more on backoff misbehaviors with significant gains.

However, little attention has been focused on quantifying the gain of backoff misbehaving nodes in the literature.

We are therefore motivated to address the problem: *how to quantify the gain of backoff misbehavior*?

#### 1 Introduction and Motivation

#### 2 Problem Statements

- Models for Backoff Misbehavior
- Definition of Order Gain

#### 3 Main Results

#### 4 Conclusion

# Two Classes of Backoff Misbehavior

Continuous misbehavior:

keeps performing misbehavior, unless disabled by countermeasures.

### Two Classes of Backoff Misbehavior

#### Continuous misbehavior:

keeps performing misbehavior, unless disabled by countermeasures.

Intermittent misbehavior:

performs misbehavior only in on state.

イロト 不得 とくほ とくほう 二日

### Continuous Misbehavior Models

- Double-window backoff misbehaving scheme  $\mathcal{B}_D$ .
- Fixed-window backoff misbehaving scheme  $\mathcal{B}_F$ .

#### Intermittent Misbehavior Model

A general Markov Chain with two states (on, off).

- on state: use any misbehaving scheme  $\mathcal{B}_m$ .
- off state: legitimate .
- on-state ratio  $\theta \in (0, 100\%)$ .

### Choose a performance metric

Our goal is to choose a performance metric to measure the gain of backoff misbehavior for CSMA/CA-based wireless networks.

# Choose a performance metric

Our goal is to choose a performance metric to measure the gain of backoff misbehavior for CSMA/CA-based wireless networks.

(日) (四) (E) (E) (E)

9/23

Candidates:

- throughput
- delay

### Choose a performance metric

Our goal is to choose a performance metric to measure the gain of backoff misbehavior for CSMA/CA-based wireless networks.

Candidates:

- throughput
- delay

But they are associated highly with protocol signals.

### Waiting Time in a Backoff Process

waiting time = 6 (slots)

イロン イヨン イヨン イヨン

3

10/23

# Waiting Time in a Backoff Process

waiting time = 6 (slots)

The resultant process consists only idle slots during the period the node contends for the channel.

The waiting time, which is the total number of counted idle slots when a node contends for the channel

• only measured by slots, therefore protocol-independent.

# Waiting Time in a Backoff Process

waiting time = 6 (slots)

The resultant process consists only idle slots during the period the node contends for the channel.

The waiting time, which is the total number of counted idle slots when a node contends for the channel

• only measured by slots, therefore protocol-independent.

Waiting time is a good metric to quantify the performance of one node in a generic CSMA/CA network.

# Order Gain Based on Waiting Time

- Waiting time: quantify performance of one node.
- Goal: performance difference between misbehaving node and legitimate node.

We need to introduce a new metric. First, define some rules on our metric  ${\cal G}.$ 

# Order Gain Based on Waiting Time

- Waiting time: quantify performance of one node.
- Goal: performance difference between misbehaving node and legitimate node.

We need to introduce a new metric. First, define some rules on our metric  ${\cal G}.$ 

- **1** Based on the waiting time.
- 2 If two nodes use the same backoff scheme, the metric should be 0.

3 The metric follows the additive rule:

■ If the gain of node A over node B is G<sub>1</sub> and the gain of node B over node C is G<sub>2</sub>,

・ロト ・ 同ト ・ ヨト ・ ヨト ・ りゅつ

• Then the gain of node A over node C:  $G_1 + G_2$ .

# Order Gain Based on Waiting Time

- Waiting time: quantify performance of one node.
- Goal: performance difference between misbehaving node and legitimate node.

We need to introduce a new metric. First, define some rules on our metric  ${\cal G}.$ 

- **1** Based on the waiting time.
- 2 If two nodes use the same backoff scheme, the metric should be 0.

3 The metric follows the additive rule:

- If the gain of node A over node B is G<sub>1</sub> and the gain of node B over node C is G<sub>2</sub>,
- Then the gain of node A over node C:  $G_1 + G_2$ .

Definition of Order Gain: The Gain of Node B over Node A

$$G(t) = \log_t \frac{P(W_A > t)}{P(W_B > t)}$$

っへで 11/23

#### Definition of Order Gain

$$G(t) = \log_t \frac{P(W_A > t)}{P(W_B > t)}$$

#### Definition of Order Gain

$$G(t) = \log_t \frac{P(W_A > t)}{P(W_B > t)}$$

Rule 1: Based on tail distribution P(W > t), e.g.,
 P(W > t) = λe<sup>-λt</sup>, P(W ≤ t) = 1 − λe<sup>-λt</sup>

#### Definition of Order Gain

$$G(t) = \log_t \frac{P(W_A > t)}{P(W_B > t)}$$

イロン 不良 とくほど 小原

■ Rule 1: Based on tail distribution P(W > t), e.g., ■  $P(W > t) = \lambda e^{-\lambda t}$ ,  $P(W \le t) = 1 - \lambda e^{-\lambda t}$ 

Rule 2 ( $W_A$  and  $W_B$  follow the same distribution) :  $\log_t \frac{P(W_A > t)}{P(W_B > t)} = 0.$ 

#### Definition of Order Gain

$$G(t) = \log_t \frac{P(W_A > t)}{P(W_B > t)}$$

- Rule 1: Based on tail distribution P(W > t), e.g., ■  $P(W > t) = \lambda e^{-\lambda t}$ ,  $P(W \le t) = 1 - \lambda e^{-\lambda t}$
- Rule 2 ( $W_A$  and  $W_B$  follow the same distribution) :  $\log_t \frac{P(W_A > t)}{P(W_B > t)} = 0.$
- Rule 3 (Additive rule):  $\log_t \frac{P(W_A > t)}{P(W_C > t)} = \log_t \frac{P(W_A > t)}{P(W_B > t)} + \log_t \frac{P(W_B > t)}{P(W_C > t)}$

#### Definition of Order Gain

$$G(t) = \log_t \frac{P(W_A > t)}{P(W_B > t)}$$

- Rule 1: Based on tail distribution P(W > t), e.g., ■  $P(W > t) = \lambda e^{-\lambda t}$ ,  $P(W \le t) = 1 - \lambda e^{-\lambda t}$
- Rule 2 ( $W_A$  and  $W_B$  follow the same distribution) :  $\log_t \frac{P(W_A > t)}{P(W_B > t)} = 0.$
- Rule 3 (Additive rule):  $\log_t \frac{P(W_A > t)}{P(W_C > t)} = \log_t \frac{P(W_A > t)}{P(W_B > t)} + \log_t \frac{P(W_B > t)}{P(W_C > t)}$

A valid metric to indicate the gain of backoff misbehavior.

2 Problem Statements

#### 3 Main Results

- Continuous Misbehavior
- Intermittent Misbehavior

# Order Gain of Continuous Misbehavior

#### Analytical Results for Continuous Misbehavior

Double-window: 
$$G_D(t) = \log_2 \frac{p}{p_D} + \Theta\left(\frac{1}{\ln t}\right),$$
  
Fixed-window:  $G_F(t) = \Theta\left(\frac{t}{\ln t}\right),$ 

where p and  $p_D$  are the collision probabilities of legitimate and double-window misbehaving nodes, respectively.

### Simulation Results for Double-Window Misbehavior

Legitimate nodes have minimum contention window  $w_0 = 16$ . The double-window misbehaving node has minimum contention window  $w_D = 6$ .

### Simulation Results for Fixed-Window Misbehavior

Legitimate nodes have minimum contention window  $w_0 = 16$ . The double-window misbehaving node has minimum contention window  $w_D = 8$ .

### Experimental Results in a WiFi Network

Experiment Setups:

- 1 Off-the-shelf 802.11b network adapter.
- 2 Metric:

Throughput gain ratio =  $\frac{\text{throughput of misbehaving node}}{\text{throughput of legitimate node}}$ .

### Experimental Results in a WiFi Network

One continuous misbehaving node chooses one of the following.

- **1** Double-window backoff misbehavior with  $W_D = 8$ .
- **2** Fix-window backoff misbehavior with  $W_F = 8$ .

#### Analytical Results for Intermittent Misbehavior

For an intermittent misbehaving node with on-state backoff scheme  $\mathcal{B}_m$  and on-state ratio  $\theta,$  its order gain satisfies

$$G_I(t) = \log_2 \frac{p_{on}}{p_{off}} + \Theta\left(\frac{1}{\ln t}\right),$$

 $p_{\scriptscriptstyle on}$  and  $p_{\scriptscriptstyle off}$  are collision probabilities of legitimate nodes in on and off states, respectively.

On-state misbehavior scheme  $\mathcal{B}_m$  is a fixed-window misbehaving scheme with  $w_{\scriptscriptstyle F}=8.$ 

On-state misbehavior scheme  $\mathcal{B}_m$  is a fixed-window misbehaving scheme with  $w_{\scriptscriptstyle F}=8.$ 

On-state misbehavior scheme  $\mathcal{B}_m$  is a fixed-window misbehaving scheme with  $w_{\scriptscriptstyle F}=8.$ 

On-state misbehavior scheme  $\mathcal{B}_m$  is a fixed-window misbehaving scheme with  $w_{\scriptscriptstyle F}=8.$ 

Key Observation: For small  $\theta$ , the order gain is not significant.

#### Experimental Results in a WiFi Network

15 legitimate nodes, 1 intermittent misbehaving node.

# Conclusions

We introduce a metric, order gain to investigate the gain of continuous misbehavior and intermittent misbehavior and perform simulations and experiments to validate our analysis.

# Conclusions

- We introduce a metric, order gain to investigate the gain of continuous misbehavior and intermittent misbehavior and perform simulations and experiments to validate our analysis.
- The number of nodes is a critical factor to the evaluation of countermeasures to backoff misbehaviors.
  - e.g., in a network with a large amount of users, countermeasure can omit double-window misbehavior and focus more on fixed-window misbehavior.

# Conclusions

- We introduce a metric, order gain to investigate the gain of continuous misbehavior and intermittent misbehavior and perform simulations and experiments to validate our analysis.
- The number of nodes is a critical factor to the evaluation of countermeasures to backoff misbehaviors.
  - e.g., in a network with a large amount of users, countermeasure can omit double-window misbehavior and focus more on fixed-window misbehavior.
- An intermittent misbehaving node with a small  $\theta$  can not achieve much gain from the network.

Thank you!
